Triggers (Oracle Version)

Often called event-condition-action rules.

- *Event* = a class of changes in the DB, e.g., "insert into `Beers`."
- *Condition* = a test as in a where-clause for whether or not the trigger applies.
- *Action* = one or more SQL statements.
- Oracle version and SQL3 version; not in SQL2.
- Differ from checks or SQL2 assertions in that:
    1. Triggers invoked by the event; the system doesn't have to figure out when a trigger could be violated.
    2. Condition not available in checks.

Example

Whenever we insert a new tuple into `Sells`, make sure the beer mentioned is also mentioned in `Beers`, and insert it (with a null manufacturer) if not.

```
Sells(bar, beer, price)

CREATE OR REPLACE TRIGGER BeerTrig
AFTER INSERT ON Sells
FOR EACH ROW
WHEN(new.beer NOT IN
            (SELECT name FROM Beers))
    BEGIN
        INSERT INTO Beers(name)
        VALUES(:new.beer);
    END;
.
run
```

Options

1. Can omit `OR REPLACE`. But if you do, it is an error if a trigger of this name exists.

2. `AFTER` can be `BEFORE`.

3. If the relation is a view, `AFTER` can be `INSTEAD OF`.

   - Useful for allowing "modifications" to a view; you modify the underlying relations instead.

4. `INSERT` can be `DELETE` or `UPDATE OF` <attribute>.

   - Also, several conditions like `INSERT ON Sells` can be connected by `OR`.

5. `FOR EACH ROW` can be omitted, with an important effect: the action is done once for the relation(s) consisting of all changes.

Notes

- More information in on-line document `or-plsql.html`
- There are two special variables `new` and `old`, representing the new and old tuple in the change.
  - `old` makes no sense in an insert, and `new` makes no sense in a delete.
- Notice: in `WHEN` we use `new` and `old` without a colon, but in actions, a preceding colon is needed.
- The action is a PL/SQL statement.
  - Simplest form: surround one or more SQL statements with `BEGIN` and `END`.
  - However, select-from-where has a limited form.

- Dot and `run` cause the definition of the trigger to be stored in the database.
  - ❖ Oracle triggers are part of the database schema, like tables or views.
- Important Oracle constraint: the action cannot change the relation that triggers the action.
  - ❖ Worse, the action cannot even change a relation connected to the triggering relation by a constraint, e.g., a foreign-key constraint.

Example

Maintain a list of all the bars that raise their price for some beer by more than $1.

```
Sells(bar, beer, price)
RipoffBars(bar)

CREATE TRIGGER PriceTrig
AFTER UPDATE OF price ON Sells
FOR EACH ROW
WHEN(new.price > old.price + 1.00)
    BEGIN
        INSERT INTO RipoffBars
        VALUES(:new.bar);
    END;
.
run
```

Modification to Views Via Triggers

Oracle allows us to "intercept" a modification to a view through an instead-of trigger.

Example

```
Likes(drinker, beer)
Sells(bar, beer, price)
Frequents(drinker, bar)
```

```
CREATE VIEW Synergy AS
    SELECT Likes.drinker, Likes.beer,
           Sells.bar
    FROM Likes, Sells, Frequents
    WHERE Likes.drinker =
           Frequents.drinker AND
        Likes.beer = Sells.beer AND
        Sells.bar = Frequents.bar;
```

```
CREATE TRIGGER ViewTrig
INSTEAD OF INSERT ON Synergy
FOR EACH ROW
    BEGIN
        INSERT INTO Likes VALUES(
            :new.drinker, :new.beer);
        INSERT INTO Sells(bar, beer)
            VALUES(:new.bar, :new.beer);
        INSERT INTO Frequents VALUES(
            :new.drinker, :new.bar);
    END;
.
run
```

SQL3 Triggers

- Read in text.
- Some differences, including:
  1. Position of `FOR EACH ROW`.
  2. The Oracle restriction about not modifying the relation of the trigger or other relations linked to it by constraints is not present in SQL3 (but Oracle is real; SQL3 is paper).
  3. The action in SQL3 is a list of SQL3 statements, not a PL/SQL statement.

SQL2 Assertions

- Database-schema constraint.
- Not present in Oracle.
- Checked whenever a mentioned relation changes.
- Syntax:

```
CREATE ASSERTION <name>
CHECK(<condition>);
```

Example

No bar may charge an average of more than \$5 for beer.

```
Sells(bar, beer, price)

CREATE ASSERTION NoRipoffBars
CHECK(NOT EXISTS(
        SELECT bar
        FROM Sells
        GROUP BY bar
        HAVING 5.0 < AVG(price)
    )
);
```

- Checked whenever `Sells` changes.

Example

There cannot be more bars than drinkers.

```
Bars(name, addr, license)
Drinkers(name, addr, phone)

CREATE ASSERTION FewBar
CHECK(
    (SELECT COUNT(*) FROM Bars) <=
    (SELECT COUNT(*) FROM Drinkers)
);
```

- Checked whenever `Bars` or `Drinkers` changes.

Class Problem

Suppose we have our usual relations

```
Beers(name, manf)
Sells(bar, beer, price)
```

and we want to maintain the foreign-key constraint that if you sell a beer, its name must appear in `Beers`.

1. If we don't have foreign-key declarations available, how could we arrange for this constraint to be maintained:
   a) Using attribute-based constraints?
   b) Using SQL2 assertions?
   c) Using Oracle triggers?
2. What if we *also* want to make sure that each beer mentioned in `Beers` is sold at at least one bar?

PL/SQL

- Found only in the Oracle SQL processor (sqlplus).
- A compromise between completely procedural programming and SQL's very high-level, but limited statements.
- Allows local variables, loops, procedures, examination of relations one tuple at a time.
- Rough form:

```
DECLARE
    declarations
BEGIN
    executable statements
END;
.
run;
```

- `DECLARE` portion is optional.
- Dot and `run` (or a slash in place of `run;`) are needed to end the statement and execute it.

Simplest Form: Sequence of Modifications

Likes(drinker, beer)

```
BEGIN
    INSERT INTO Likes
        VALUES('Sally', 'Bud');
    DELETE FROM Likes
        WHERE drinker = 'Fred' AND
            beer = 'Miller';
END;
.
run;
```

Procedures

Stored database objects that use a PL/SQL statement in their body.

Procedure Declarations

```
CREATE OR REPLACE PROCEDURE
    <name>(<arglist>) AS
            <declarations>
        BEGIN
            <PL/SQL statements>
        END;
.
run;
```

- Argument list has name-mode-type triples.
  - ❖ Mode: IN, OUT, or IN OUT for read-only, write-only, read/write, respectively.
  - ❖ Types: standard SQL + generic types like `NUMBER` = any integer or real type.
  - ❖ Since types in procedures *must* match their types in the DB schema, you should generally use an expression of the form

    relation.attribute`%TYPE`

    to capture the type correctly.

Example

A procedure to take a beer and price and add it to Joe's menu.

```
Sells(bar, beer, price)

CREATE PROCEDURE joeMenu(
    b IN Sells.beer%TYPE,
    p IN Sells.price%TYPE
) AS
    BEGIN
        INSERT INTO Sells
        VALUES('Joe''s Bar', b, p);
    END;
.
run;
```

- Note "run" only stores the procedure; it doesn't execute the procedure.

Invoking Procedures

A procedure call may appear in the body of a PL/SQL statement.

- Example:

```
BEGIN
    joeMenu('Bud', 2.50);
    joeMenu('MooseDrool', 5.00);
END;
.
run;
```
