### SQL Queries

• Principal form:

SELECT desired attributes FROM tuple variables range over relations WHERE condition about t.v.'s;

Running example relation schema:

Beers(<u>name</u>, manf)
Bars(<u>name</u>, addr, license)
Drinkers(<u>name</u>, addr, phone)
Likes(<u>drinker</u>, <u>beer</u>)
Sells(<u>bar</u>, <u>beer</u>, price)
Frequents(<u>drinker</u>, <u>bar</u>)

#### Example

What beers are made by Anheuser-Busch?

```
Beers(<u>name</u>, manf)
SELECT name
FROM Beers
WHERE manf = 'Anheuser-Busch';
```

• Note single quotes for strings.

name
Bud
Bud Lite
Michelob

# Formal Semantics of Single-Relation SQL Query

- 1. Start with the relation in the FROM clause.
- 2. Apply  $\sigma$ , using condition in WHERE clause.
- 3. Apply  $\pi$  using attributes in SELECT clause.

### **Equivalent Operational Semantics**

Imagine a *tuple variable* ranging over all tuples of the relation. For each tuple:

- Check if it satisfies the WHERE clause.
- Print the attributes in SELECT, if so.

#### **Star as List of All Attributes**

Beers(<u>name</u>, manf)

SELECT \*
FROM Beers
WHERE manf = 'Anheuser-Busch';

name	$\operatorname{manf}$
Bud	Anheuser-Busch
Bud Lite	Anheuser-Busch
Michelob	Anheuser-Busch

#### **Renaming columns**

Beers(<u>name</u>, manf)

SELECT name AS beer
FROM Beers
WHERE manf = 'Anheuser-Busch';

beer

Bud Bud Lite Michelob **Expressions as Values in Columns** 

Sells(<u>bar</u>, <u>beer</u>, price)
SELECT bar, beer,
 price\*106 AS priceInYen
FROM Sells;

bar	beer	$\operatorname{priceInYen}$
Joe's Sue's 	Bud Miller 	$\begin{array}{c} 265\\ 318\\ \ldots \end{array}$

• Note no WHERE clause OK.

• Trick: If you want an answer with a particular string in each row, use that constant as an expression.

```
Likes(drinker, beer)
SELECT drinker,
    'likes Bud' AS whoLikesBud
FROM Likes
WHERE beer = 'Bud';
```

drinker	whoLikesBud
Sally Fred	likes Bud likes Bud
• • •	• • •

### Example

Find the price Joe's Bar charges for Bud.

```
Sells(<u>bar</u>, <u>beer</u>, price)
SELECT price
FROM Sells
WHERE bar = 'Joe''s Bar' AND
        beer = 'Bud';
```

- Note: two single-quotes in a character string represent one single quote.
- Conditions in WHERE clause can use logical operators AND, OR, NOT and parentheses in the usual way.
- Remember: SQL is *case insensitive*. Keywords like SELECT or AND can be written upper/lower case as you like.
  - Only inside quoted strings does case matter.

### Patterns

- % stands for any string.
- \_ stands for any one character.
- "Attribute LIKE pattern" is a condition that is true if the string value of the attribute matches the pattern.

Also NOT LIKE for negation.

#### Example

Find drinkers whose phone has exchange 555.

Drinkers(<u>name</u>, addr, phone) SELECT name FROM Drinkers WHERE phone LIKE '%555-\_\_\_';

• Note patterns must be quoted, like strings.

# Multirelation Queries

- List of relations in FROM clause.
- Relation-dot-attribute disambiguates attributes from several relations.

## Example

Find the beers that the frequenters of Joe's Bar like.

```
Likes(<u>drinker</u>, <u>beer</u>)
Frequents(<u>drinker</u>, <u>bar</u>)
SELECT beer
FROM Frequents, Likes
WHERE bar = 'Joe''s Bar' AND
Frequents.drinker = Likes.drinker;
```

# Formal Semantics of Multirelation Queries

Same as for single relation, but start with the product of all the relations mentioned in the FROM clause.

## **Operational Semantics**

Consider a tuple variable for each relation in the FROM.

- Imagine these tuple variables each pointing to a tuple of their relation, in all combinations (e.g., nested loops).
- If the current assignment of tuple-variables to tuples makes the WHERE true, then output the attributes of the SELECT.

Likes

Frequents

# Explicit Tuple Variables

Sometimes we need to refer to two or more copies of a relation.

• Use *tuple variables* as aliases of the relations.

## Example

Find pairs of beers by the same manufacturer.

- SQL2 permits AS between relation and its tuple variable; Oracle 8 does not.
- Note that b1.name < b2.name is needed to avoid producing (Bud, Bud) and to avoid producing a pair in both orders.

# Subqueries

Result of a select-from-where query can be used in the where-clause of another query.

### Simplest Case: Subquery Returns a Single, Unary Tuple

Find bars that serve Miller at the same price Joe charges for Bud.

```
Sells(<u>bar</u>, <u>beer</u>, price)
SELECT bar
FROM Sells
WHERE beer = 'Miller' AND
price =
   (SELECT price
   FROM Sells
   WHERE bar = 'Joe''s Bar' AND
        beer = 'Bud'
   );
```

- Notice the *scoping rule*: an attribute refers to the most closely nested relation with that attribute.
- Parentheses around subquery are essential.

#### The IN Operator

"Tuple IN relation" is true iff the tuple is in the relation.

### Example

Find the name and manufacturer of beers that Fred likes.

```
Beers(<u>name</u>, manf)
Likes(<u>drinker</u>, <u>beer</u>)
SELECT *
FROM Beers
WHERE name IN
  (SELECT beer
   FROM Likes
   WHERE drinker = 'Fred'
  );
```

• Also: NOT IN.

EXISTS

"EXISTS(relation)" is true iff the relation is nonempty.

#### Example

Find the beers that are the unique beer by their manufacturer.

```
Beers(<u>name</u>, manf)
SELECT name
FROM Beers b1
WHERE NOT EXISTS(
    SELECT *
    FROM Beers
    WHERE manf = b1.manf AND
        name <> b1.name
);
```

- Note scoping rule: to refer to outer Beers in the inner subquery, we need to give the outer a tuple variable, b1 in this example.
- A subquery that refers to values from a surrounding query is called a *correlated subquery*.

## Quantifiers

ANY and ALL behave as existential and universal quantifiers, respectively.

• Beware: in common parlance, "any" and "all" seem to be synonyms, e.g., "I am fatter than any of you" vs. "I am fatter than all of you." But in SQL:

### Example

Find the beer(s) sold for the highest price.

```
Sells(<u>bar</u>, <u>beer</u>, price)
SELECT beer
FROM Sells
WHERE price >= ALL(
    SELECT price
    FROM Sells
);
```

### Class Problem

Find the beer(s) not sold for the lowest price.
